

Western Dragon: Descriptive

Overview

Western Dragons possess both four legs and wings, which makes it difficult to identify them in the animal kingdom, especially among the vertebrates, which remain exclusively tetrapods. All species known to science that have solved the solution to the Flight Problem have been vertebrates as well.

Descriptions of Western dragons vary greatly, from depictions of Saint George and the dragon with the monster being smaller than a horse, to descriptions of dragons being a dozen feet (3.65 m) long to fifty feet (15.24 m) long.

Common traits of Western Dragons include the following:

- Reptilian appearance
- Wings and/or the Ability to Fly
- Tremendous Strength and/or Powerful Muscles
- Heavy Bodies, Terrible Jaws and Teeth
- Noxious Breath and/or the ability to spew water, fire, or venom
- Dangerous, even poisonous, blood

Some less than common traits of Western Dragons, yet still applicable in consideration, include the following:

- Association with a protected area, especially mountains or rocky regions or even bodies of water
- Fabulous Eyes
- Association with dangerous geography, such as volcanoes
